CCPS 530 - Web Systems Development - Lab 8

1. Enhance the express URI (/bookinventory/add) to insert a book into a MongoDB collection.

- The code was refactored to add a document to a MongoDB database (db = 'ccps530_lab7', collection = 'book') instead of adding it to a JSON variable

```
app.post('/bookinventory/addbook', function (req, res) {
  const client = new MongoClient(uri);

  var new_doc = {
    'title': req.body.title,
    'author': req.body.author,
    'publisher': req.body.publisher,
    'date': req.body.date,
    'website': req.body.website
  };

  async function addBook() {
    try {
      const db = client.db(dbname);
      const coll = db.collection(collname);

      const query = await coll.insertOne(new_doc);
      console.log('1 document inserted');
      res.send('<h1>Andrew Parsons Book Inventory</h1><ul><li><a href="/">Home Page</a></li><li><a href="/bookinventory/list">Current Book List</a></li><li><a href="/bookinventory/add">Add Another Book</a></li></ul><h2>Title: ' + req.body.title + ' is added!</h2>');
    } finally {
      // Ensures that the client will close when you finish/error
      await client.close();
    }
  }

  addBook().catch(console.dir);
});
```

2. Enhance the express URI (/bookinventory/list) to retrieve all books from a MongoDB collection.

- The code was refactored to pull all documents from a MongoDB database (db = 'ccps530_lab7', collection = 'book') instead of printing the results of a stored JSON variable.

```
app.get('/bookinventory/list', function (req, res) {
  const client = new MongoClient(uri);
  var bookinventory = [];
  async function getBookInventory() {
    try {
      const db = client.db(dbname);
      const coll = db.collection(collname);

      bookinventory = await coll.find({}).toArray();
      var html = '<p>'
      for (var i = 0; i < bookinventory.length; i++) {
        html = html + 'Title: ' + bookinventory[i].title + '<br>';
        html = html + 'Author: ' + bookinventory[i].author + '<br>';
        html = html + 'Publisher: ' + bookinventory[i].publisher + '<br>';
        html = html + 'Date: ' + bookinventory[i].date + '<br>';
        html = html + 'Website: ' + bookinventory[i].website + '<br>';
        html = html + '<br>';
      }
      html += '</p>'

      res.send('<h1>Andrew Parsons Book Inventory</h1><ul><li><a href="/">Home Page</a></li><li><a href="/bookinventory/add">Add a Book</a></li></ul><h2>Current Book List: </h2>' + html);
    } finally {
      // Ensures that the client will close when you finish/error
      await client.close();
    }
  }
  getBookInventory().catch(console.dir);
});
```

Technical Report

1. Write a technical report explaining your design choices and what you used to test the RESTful endpoints from numbers 1 and 2.
 - The key to designing the code in Lab 8 was to understand how to combine the code from Lab 6 and 7 in a way that could replace using a local JSON file with a call to the MongoDB collection.
 - This involved wrapping an async function within each of the relevant **app.get()** Express calls, and submitting the html response only after the database function had been called and completed.
 - One key aspect that took a bit of testing was to realize that the MongoClient(uri) object had to be re-instantiated for every call to the DB - and it too had to be wrapped within the **app.get()** Express call.
 - Additionally, the entirety of the HTML response had to be wrapped within the body of the **async function** to the MongoDB collection to ensure that the async call had been completed prior to populating the HTML for the Express URI - otherwise it threw errors as the result of a race condition.
 - See code from responses to 1 and 2 above for specific implementation.
2. How long did you spend on this lab? The length of time includes readings and research and code experimentation. State time involved in readings and research as well as code experimentation sessions.
 - I spent approximately 2.5 hours working on this lab.
 - It took about 2 hours to merge the code from labs 6 and 7, as well as finding the correct syntax in order to return all documents from a MongoDB collection. After that it was mostly rearranging the order of the code in order to ensure all functions and responses fired correctly and within the scope that was required.
 - It then took about another 30 minutes to do the validation, take screenshots, write up the technical report, etc.
